

Interim Stabilization Therapy (IST)

CDHBC Position Statement

July 2015

Interim Stabilization Therapy (IST) is a temporary restorative procedure which arrests dental decay through a therapeutic release of fluoride, leading to remineralization of the interface layer between the dentin and the temporary cement, thereby stabilizing the tooth structure until a permanent restoration can be placed. This procedure was adopted in 2010 by the Ontario Region First Nations Inuit Health Branch to arrest disease in children in high risk communities in Northern Ontario¹ however it may have applicability in a much broader population of individuals with limited access to dental care, including adults and the frail or elderly.

IST can be distinguished from ART (atraumatic restorative therapy) by the fact that IST does not call for the removal of sound tooth structure in order to recontour margins, whereas ART is characterized by using a hand chisel to remove enamel rods to roughly prepare the cavity. IST requires that any soft foreign material or debris be removed from the tooth prior to the placement of the temporary restorative resin (glass ionomer cement) in order to facilitate the bonding of the material to tooth structure.

The CDHBC Board has carefully reviewed the history and application of the IST procedure and has determined that IST is not outside the current Scope of Practice for dental hygienists registered in BC. Registered Dental Hygienists in BC may place temporary restorations including provisional prosthodontic restorations as per the CDHBC Scope of Practice², provided that appropriate education has been obtained. However, removal of sound tooth structure is not within the dental hygiene Scope of Practice in BC.

The therapy's stabilizing benefits are particularly beneficial to vulnerable populations including the frail and the elderly and those populations with limited access to dental care. In reviewing the applicability of IST to various BC populations, the CDHBC Board established that it would be appropriate to provide IST to vulnerable individuals who have limited access to dental treatment, which may include children, the frail and the elderly. Limited access to care could be due to a variety of reasons including financial limitation or inhabiting rural or remote communities where a dentist is not present.

Given that the IST process is based on a careful determination of appropriate teeth to treat under specific circumstances, often in remote and underserved areas, the CDHBC Board concluded that delivery of this treatment must be carried out by dental hygienists who currently hold 365 Exempt Registration. Dental hygienists who are employed in traditional office settings will be able to collaborate with dental practitioners to offer clients appropriate and permanent restorative treatments, thereby negating the applicability of IST as a necessary temporary measure. Furthermore, if a client cannot access a dentist, it is unlikely that client has received a dental exam within the previous year; therefore they would not meet the 365 Day Rule requirements for Full or Conditional registrants. 365 Exempt registrants are best positioned to access the vulnerable populations who will benefit most from IST through mobile practices and long term care settings.

By virtue of its primary function, IST is a temporary stabilizing therapy, which is intended to provide the client with temporary relief and improved tooth integrity until a permanent restoration can be placed by a dentist. All clients who are treated with IST must be referred immediately to a dental practitioner for

further consultation and treatment. It is the responsibility of the dental hygienist to ensure that a referral is provided and that the client understands the importance of imminent follow-up care.

To perform IST, dental hygienists must have completed appropriate, IST-specific education and comply with all CDHBC Regulations³ and Practice Standards⁴. While dental hygienists may not diagnose decay, an identification of the client's unmet needs according to the *Human Needs Conceptual Model of Care*⁵ supports the therapeutic intervention of IST where the unmet need of biologically sound dentition would be addressed by temporarily stabilizing the tooth. To ensure appropriate and comprehensive treatment is provided, IST must be performed as part of the Dental Hygiene Process of Care and clients who receive this treatment must be referred to a dental practitioner for follow-up restorative treatment.

The CDHBC does not endorse specific educational opportunities and encourages dental hygienists to exercise professional discretion in determining their competence and capability in applying a new skill to their dental hygiene practice.
